

HealthConnect Cross-track Integration Report

Date: 11/09/2026

Analyst: Poloko Dignity Ranna

Dataset: HealthConnect Appointment Dataset

Data Science Track Integration

Information/Output Received: The formal evaluation results of my week 5 findings. They engineered features based on insights (far_with_reminder, age_gender_group), tested them in their model, and reported the outcome

Information/Output Provided: Deeper analysis file with detailed statistical validation of my main findings, and the definition and justification for the new "Previous No-show Rate" KPI.

Integration Activity Completed: Translated week 5 data analytics findings into concrete testable features

Data Analysis to Feature Engineering: The DS track translated Ranna's DA findings into concrete, testable features which were integrated into a logistic regression model and formally evaluated against the baseline

What Changed as a Result: The statistical findings were validated as being correct in the context of prediction, but their practical application was refined. The recommendation for the 30-40km group shifted from "optimize reminders" to "offer transportation/logistical support," which is a much more precise and effective business action.

Evidence of Integration

Evidence includes the Model Improvement & Validation file, which was shared with the Data Analytics track. The subsequent reproduction of the 30-40km/reminder pattern in their dataset (78.7% vs my independently found 77%), the engineering of two features (far_with_reminder and age_gender_group) directly from my findings, and their formal model evaluation showing neither feature improved performance, followed by my Week 6 statistical work explaining why (logistical barriers, not reminder interaction) is the primary proof of integration.
